## HIGHLIGHTS

- $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod exhibited the high catalytic activity of  $\text{CH}_2\text{Br}_2$  oxidation.
- $\text{CeO}_2$  morphology strongly affected  $\text{Co}_3\text{O}_4$ - $\text{CeO}_2$  interactions and structures of  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts.
- $\text{Co}^{3+}$  species, surface-adsorbed oxygen and oxygen vacancies were most abundant on  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod.
- The reaction mechanism for  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts was proposed.

## ABSTRACT

Brominated hydrocarbons are a typical pollutant in purified terephthalic acid (PTA) exhaust gas, which is harmful for human health and the environment once released to the atmosphere. In this study, three  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts with different  $\text{CeO}_2$  morphologies (rod, plate, and cube) were prepared and were used for low temperature dibromomethane ( $\text{CH}_2\text{Br}_2$ ) oxidation, which was used as the model compound for brominated hydrocarbons. The experimental results showed that  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod achieved significantly higher catalytic activity, with a T-90 of approximately 312 °C for  $\text{CH}_2\text{Br}_2$  oxidation and higher selectivity to  $\text{CO}_2$  than  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube. All of the  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated were stable for at least 30 h at 500 ppm  $\text{CH}_2\text{Br}_2$  and 10%  $\text{O}_2$  at a GHSV of 75,000  $\text{mL}/(\text{g}\cdot\text{h})^{-1}$ , and the final products were  $\text{CO}_x$ ,  $\text{Br}_2$ , and  $\text{HBr}$ , without the formation of other Br-containing organic byproducts. The higher catalytic activity of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod was attributed to the high content of  $\text{Co}^{3+}$ , more surface-adsorbed oxygen, and more oxygen vacancies in their exposed {100} and {110} planes. In addition,  $\text{Co}_3\text{O}_4$  had a stronger interaction with  $\text{CeO}_2$ -rod, making it superior for  $\text{CH}_2\text{Br}_2$  oxidation. Moreover, on the basis of the analysis of products and *in situ* DRIFTS studies, a credible reaction mechanism for  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts was proposed.

## 1. Introduction

Volatile organic compounds (VOCs) not only are recognized as one of potent and important contributors to air pollution [1], but also put human health and the environment at risk [2]. Particu-

larly, increasing attention is being paid to purified terephthalic acid (PTA) exhaust gas because of its high toxicity and difficulty of treatment [3], and the staging of massive protests against such projects in China in recent years. The PTA exhaust gas contains various organic compounds, such as p-xylene (PX), brominated hydrocarbons, and acetic acid methyl ester [4]. Among all of the treatment methods, catalytic oxidation is one of the most popular methods to treat PTA exhaust gas, by reason of its low energy

E-mail address: [nqyan@sjtu.edu.cn](mailto:nqyan@sjtu.edu.cn) (N. Yan).

consumption and lower contents of secondary pollutants [5]. Nevertheless, the existence of brominated hydrocarbons in PTA exhaust gas demands that the catalyst must have the ability to resist bromine-poisoning. Therefore, the key issue in this method is to develop a high-performance catalyst to remove brominated hydrocarbons.

Currently, researchers are mainly focusing on two types of catalysts for brominated hydrocarbons oxidation, including noble metals [6] and transition metal oxides [3]. In spite of noble metal catalysts display prominent catalytic activity, the low resistance to bromine-poisoning and high cost limits their industrial applications. In contrast, transition metal oxide catalysts have gained increasing attention on account of their low cost, high catalytic activity, and high stability to brominated hydrocarbons oxidation. Thus, it is of great interest to develop transition metal oxide catalysts for brominated hydrocarbons oxidation.

Among many transition metal oxides, the Co-based catalyst has been proven to have a good catalytic performance for brominated hydrocarbons oxidation [7]. However, the catalytic activity, product-selectivity, and stability of the Co-based catalyst need to be further improved. CeO<sub>2</sub> is often used as a support in the catalytic reaction, such as CuO/CeO<sub>2</sub> [8], Au/CeO<sub>2</sub> [9], and FeOOH/CeO<sub>2</sub> [10], by reason of its prominent oxygen mobility [11], high oxygen storage capacity [12], and some acidic properties [13]. In addition, CeO<sub>2</sub> as a support can promote the dispersion of metal oxides and increase the metal-support interaction [14]. In the past few years, it has been found that the catalytic performance of CeO<sub>2</sub> is affected by exposed lattice planes [15]. Generally, different lattice planes are exposed in different CeO<sub>2</sub> morphologies. For instance, CeO<sub>2</sub> nanorods are prone to expose two {100} planes and four {110} planes [16], while CeO<sub>2</sub> nanocubes expose six {100} planes [17]. On the basis of density functional theory, the chemical activities of the different CeO<sub>2</sub> planes follow the order: {111} < {100} < {110} [18], which reveals that it is easier to produce oxygen vacancies on the CeO<sub>2</sub> {110} plane. Until now, there have been many reports about morphology effects of the CeO<sub>2</sub> support on dry-reforming of methane [18] and oxidation of CO [19]. It is reported that Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts have been studied in the field of catalysis due to their unique physicochemical properties. For example, Guo et al. reported that Co<sub>3</sub>O<sub>4</sub>/meso-CeO<sub>2</sub> had a good catalytic performance for CO preferential oxidation in H<sub>2</sub>-rich gases because of the high dispersion of cobalt oxides on meso-CeO<sub>2</sub> supports [20]. Tian et al. found that (Co<sub>3</sub>O<sub>4</sub>)<sub>50%</sub>/CeO<sub>2</sub> had a better reducibility and activity oxygen species, which coincided with its high catalytic activity for CO oxidation [21]. However, research about Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts, relating the effect of CeO<sub>2</sub> morphology on the catalytic performance for brominated hydrocarbons oxidation, is rare.

In this study, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts with different CeO<sub>2</sub> morphologies (rod, plate, and cube) were prepared and were used for dibromomethane (CH<sub>2</sub>Br<sub>2</sub>) oxidation, which was chosen as the model compound for brominated hydrocarbons. The physicochemical properties of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts with different CeO<sub>2</sub> morphologies were studied. The CH<sub>2</sub>Br<sub>2</sub> conversion, analysis of products, and catalyst stability were also investigated. On the basis of the analysis of products and *in situ* DRIFTS studies, a credible reaction mechanism for CH<sub>2</sub>Br<sub>2</sub> oxidation over Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts was proposed.

## 2. Experimental section

### 2.1. Catalyst preparation

CeO<sub>2</sub> nanorods and nanocubes were prepared by the hydrothermal method. Typically, 3.48 g Ce(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O and 19.2 g NaOH

were dissolved in 40 mL ultrapure water, respectively. Next, the NaOH solution was dripped into the Ce(NO<sub>3</sub>)<sub>3</sub> solution, and the mixed solution was magnetic stirred for 60 min. Then, the mixed solution was transferred into a stainless steel reaction kettle with Teflon lining and maintained at constant temperatures (rods: 100 °C; and cubes: 180 °C) for 24 h.

CeO<sub>2</sub> nanoplates were prepared by the CTAB (Cetyltrimethyl Ammonium Bromide)-assisted hydrothermal method. Typically, 0.73 g CTAB and 2.61 g Ce(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O were dissolved in 80 mL ultrapure water and magnetic stirred for 30 min. Subsequently, 8 mL NH<sub>3</sub>·H<sub>2</sub>O was dripped into the mixed solution and magnetic stirred for 30 min, and then the mixed solution was transferred into a stainless steel reaction kettle with Teflon lining and maintained at 100 °C for 24 h.

After filtering and washing with ultrapure water, the obtained precipitates were dried at 60 °C for 12 h, and then calcined at 500 °C for 3 h in air.

Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts with different CeO<sub>2</sub> morphologies (rod, plate, and cube) were prepared by the impregnation method. CeO<sub>2</sub> powders were mixed with Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O solution under magnetic stirring at 60 °C to gain Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> (5 wt% Co/CeO<sub>2</sub>). The samples were dried at 60 °C for 12 h, and then calcined at 500 °C for 3 h in air. The samples were flagged as CeO<sub>2</sub>-rod, CeO<sub>2</sub>-plate, CeO<sub>2</sub>-cube, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube.

### 2.2. Catalyst characterization

X-ray diffraction (XRD) were performed on the Shimadzu XRD-6100, and the diffractograms were obtained in the 2θ range of 10°–80°, with a scanning velocity of 10°/min. The N<sub>2</sub> adsorption-desorption isotherms were collected using a physical adsorption instrument (Nova 2200e) at –196 °C. Before each experiment, the samples were pretreated under the condition of vacuum at 200 °C for 3 h. The specific surface area was obtained by the multipoint BET model. Raman spectra were recorded on a SENTERRA R200 microscope. The excitation source was the 532 nm line of Ar ion laser. The morphology of the samples was observed using transmission electron microscopy (TEM) (JEOL-2100F) and scanning electron microscope (SEM) (JSM-7800F). Before each experiment, the samples were evenly dispersed in ethanol solution under the condition of ultrasound. Chemical analysis of the samples was performed on the inductively coupled plasma (ICP) spectrometer with iCAP 6000 Radial. The H<sub>2</sub>-TPR experiments were performed on an automatic chemical adsorption instrument (AutoChem II, 2920). Before each experiment, the 100 mg samples were degassed in Ar flow at 300 °C for 2 h. Subsequently, after cooling to 100 °C, the samples were heated up to 1000 °C in 10% H<sub>2</sub>/Ar flow, with a heating rate of 10 °C/min. The NH<sub>3</sub>-TPD experiments were also performed on an automatic chemical adsorption instrument (AutoChem II, 2920). Before each experiment, the 500 mg samples were degassed in He flow at 300 °C for 2 h. Then, after cooling to 50 °C, NH<sub>3</sub> adsorption was performed in 10% NH<sub>3</sub>/He flow at 50 °C for 1 h. Subsequently, the samples were treated in He flow for 30 min to remove gaseous NH<sub>3</sub>, and then heated up to 800 °C in He flow, with a heating rate of 10 °C/min. X-ray photoelectron spectroscopy (XPS) was carried out on a PHI-5300 (PE) spectrometer using Mg Ka radiation as the excitation source, the binding energy was calibrated using the C 1 s line at 284.8 eV as an internal standard.

### 2.3. Catalytic performance evaluation

The catalytic performance for CH<sub>2</sub>Br<sub>2</sub> oxidation was investigated by a fixed-bed flow reactor (i.d. 6 mm). 120 mg catalyst was placed in the middle of the reactor using silica wool. The gas

mixture contained 500 ppm  $\text{CH}_2\text{Br}_2$ , 10%  $\text{O}_2$ , 0 or 2%  $\text{H}_2\text{O}$ , 0 or 500 ppm p-xylene (PX), and  $\text{N}_2$  as the balance. The gaseous  $\text{CH}_2\text{Br}_2$  was produced by a nitrogen-blowing method, passing  $\text{N}_2$  flow through a bottle containing pure  $\text{CH}_2\text{Br}_2$  in a thermostatic oil bath. The gaseous  $\text{H}_2\text{O}$  and PX were produced by the same method, respectively. The total gas flow was 150 mL/min, giving a gas hourly space velocity (GHSV) of  $75,000 \text{ mL}/(\text{g}\cdot\text{h})^{-1}$ . The range of catalytic temperatures was from 150 to  $450^\circ\text{C}$ . The concentration of  $\text{CH}_2\text{Br}_2$  was monitored by a GC-9790 equipped with a FID, and the data were collected at each evaluated temperature after stabilizing for 30 min. The catalytic activity was evaluated in terms of  $\text{CH}_2\text{Br}_2$  conversion, defined as follows:

$$X_{\text{CH}_2\text{Br}_2} = \frac{C_{\text{in}} - C_{\text{out}}}{C_{\text{in}}} \times 100\% \quad (1)$$

where  $C_{\text{in}}$  and  $C_{\text{out}}$  are the  $\text{CH}_2\text{Br}_2$  concentrations corresponding to the inlet and outlet, respectively.

The outlet gas products were determined by a GCMS-QP2010. The concentrations of  $\text{Br}_2$  and HBr were determined by the titration method. The gas containing  $\text{Br}_2$  and HBr was first absorbed in a KI solution of a certain concentration. Next, the concentration of  $\text{Br}_2$  was determined by the titration using  $\text{Na}_2\text{S}_2\text{O}_3$  solution with starch solution as an indicator. The concentration of bromide ions in the absorbed solution was determined by an ion chromatography. The concentrations of CO and  $\text{CO}_2$  were monitored by a GC-14B equipped with a FID and a methane conversion oven. The selectivity to CO,  $\text{CO}_2$ ,  $\text{Br}_2$ , and HBr were defined as follows, respectively:

$$S_{\text{CO}} = \frac{C_{\text{CO}}}{C_{\text{in}} - C_{\text{out}}} \times 100\% \quad (2)$$

$$S_{\text{CO}_2} = \frac{C_{\text{CO}_2}}{C_{\text{in}} - C_{\text{out}}} \times 100\% \quad (3)$$

$$S_{\text{Br}_2} = \frac{C_{\text{Br}_2}}{C_{\text{in}} - C_{\text{out}}} \times 100\% \quad (4)$$

$$S_{\text{HBr}} = \frac{C_{\text{HBr}}}{2(C_{\text{in}} - C_{\text{out}})} \times 100\% \quad (5)$$

where  $C_{\text{CO}}$  and  $C_{\text{CO}_2}$  are the concentrations of CO and  $\text{CO}_2$  (ppm) in the outlet,  $C_{\text{Br}_2}$  and  $C_{\text{HBr}}$  are the concentrations of  $\text{Br}_2$  and HBr (ppm) in the outlet.

#### 2.4. In situ DRIFTS studies

In situ DRIFTS experiments were carried out on a Fourier transform infrared spectrometer (FTIR, Nicolet 6700) fitted with a MCT detector. The DRIFTS cell was fitted with ZnSe windows and a heating chamber. Real reaction conditions were simulated by a temperature controller and mass flow controllers. The in situ DRIFTS spectra were collected in the range of  $4000\text{--}800 \text{ cm}^{-1}$  at a resolution of  $4 \text{ cm}^{-1}$  and over 100 scans. Prior to each experiment, the samples were pretreated with 10%  $\text{O}_2/\text{N}_2$  at  $400^\circ\text{C}$  for 2 h to remove surface contaminants, and then cooled to  $50^\circ\text{C}$ . Spectra of the clean catalyst surface were collected and used as the background. Next, a gas stream containing 500 ppm  $\text{CH}_2\text{Br}_2/10\% \text{ O}_2/\text{N}_2$  was exposed to the DRIFTS cell at  $50^\circ\text{C}$  for 1 h. Finally, the catalyst was treated in 10%  $\text{O}_2/\text{N}_2$  from 50 to  $400^\circ\text{C}$ . In situ DRIFTS spectra were collected from 50 to  $400^\circ\text{C}$ .

### 3. Results and discussion

#### 3.1. Catalytic performance

The activity of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated for  $\text{CH}_2\text{Br}_2$  oxidation is shown in Fig. 1. It is obvious that  $\text{CH}_2\text{Br}_2$  conversion over all of the catalysts increased with the increase of temperature, and an apparent difference in the activity was also found. Pure  $\text{CeO}_2$  supports exhibited considerable activity, particularly, the activity of  $\text{CeO}_2$ -rod was the highest among the three  $\text{CeO}_2$  supports, with a T-90 (the temperature needed for 90% conversion) of approximately  $370^\circ\text{C}$ , followed by  $\text{CeO}_2$ -plate and by  $\text{CeO}_2$ -cube, which was the least active. With the addition of Co, the activity was significantly improved and the conversion curves shifted to lower temperatures.  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod exhibited the highest activity, with a T-90 of approximately  $312^\circ\text{C}$ , followed by  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate and by  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube, which was the least active.

#### 3.2. Catalyst characterization

Fig. 2 shows the TEM and HRTEM images of  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts with different  $\text{CeO}_2$  morphologies. The TEM images indicated that the three different  $\text{CeO}_2$  catalysts still kept their original morphologies after the addition of Co. Fig. 2a displayed that  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod was composed of nanorods with a width of approximately 10 nm and length varying from 20 to 100 nm. According to the HRTEM image (Fig. 2b), two types of lattice fringe directions, corresponded to (220) and (200) planes, were found for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod, which had interplanar spacing of 0.19 and 0.27 nm, respectively. Therefore,  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod grew along the [110] direction and mainly exposed the unstable {110} and {100} planes [22]. The TEM image of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate displayed that it consisted of hexagonal plates with a diameter of approximately 18 nm (Fig. 2c). The HRTEM image in Fig. 2d displayed that the lattice fringe attributed to the (111) plane, with an interplanar spacing of 0.32 nm, belonged to the {111} plane [23]. The  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube was cube with uneven size varying from 15 to 60 nm. The HRTEM image in Fig. 2f displayed that the lattice fringe assigned to the (200) plane with an interplanar spacing of 0.27 nm, belonged to the {100} plane. The morphology of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube matched with that of a cube exposed by six {100} planes [24]. Interestingly, the lattice fringes attributed to  $\text{Co}_3\text{O}_4$  were not observed for all three  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts, indicating

Fig. 1. Conversion curves for  $\text{CH}_2\text{Br}_2$  oxidation as a function of temperature over the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated.

**Fig. 2.** TEM and HRTEM images of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod (a, b),  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate (c, d), and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube (e, f).

that  $\text{Co}_3\text{O}_4$  had a good dispersion on the surface of all three  $\text{CeO}_2$  supports. To further obtain the morphology information of  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts with different  $\text{CeO}_2$  morphologies, SEM experiment was also conducted, and the images of SEM (Fig. S1) were consistent with those of TEM. The above results revealed that the desired morphologies of  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts with different  $\text{CeO}_2$  planes were successfully synthesized.

Fig. 3 shows the XRD patterns of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated. The diffraction peaks at 28.5, 33.0, 47.5, 56.3, 59.1, 69.4, 76.8, and 79.1° were ascribed to the face-centered cubic fluorite structure of  $\text{CeO}_2$  in all of the samples [25]. Interestingly, only a very weak peak at 36.9°, assigned to  $\text{Co}_3\text{O}_4$  [26], was observed in  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts, indicating thorough dispersion of  $\text{Co}_3\text{O}_4$  or amorphous Co-containing species on the  $\text{CeO}_2$  supports.

The chemical compositions of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated were measured by ICP and the results were listed

in Table 1. Co/ $\text{CeO}_2$  mass ratios of the three  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts were basically consistent with the nominal values. The  $\text{N}_2$  adsorption-desorption isotherm and pore size distribution of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated are shown in Fig. S2, and the physical properties estimated by  $\text{N}_2$  physisorption were also listed in Table 1. As shown in Fig. S2(a), the  $\text{N}_2$  adsorption-desorption isotherms of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated were assigned to type IV with a type H3 hysteresis loop at high relative pressure. As shown in Fig. S2(b), it was found that the pore size distribution of the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated was not uniform and all the  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated had porosity structures. As listed in Table 1, the average pore size of  $\text{CeO}_2$ -rod,  $\text{CeO}_2$ -plate, and  $\text{CeO}_2$ -cube were 25.1, 23.4, and 19.8 nm, respectively. With the addition of Co, the average pore size became small and decreased to 24.9, 22.2, and 18.3 nm for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod,  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate, and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube, respectively. In addition, the pore size of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod,

Fig. 3. XRD patterns of the CeO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated.

Fig. 4. Raman spectra of the CeO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated.

Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube was centered on approximately 3, 10, and 25 nm, respectively. Moreover, the specific surface area of CeO<sub>2</sub>-rod, CeO<sub>2</sub>-plate, and CeO<sub>2</sub>-cube were 67.1, 52.9, and 26.8 m<sup>2</sup> g<sup>-1</sup>, respectively. After the addition of Co, the specific surface area of CeO<sub>2</sub>-rod, CeO<sub>2</sub>-plate, and CeO<sub>2</sub>-cube decreased to 58.9, 44.7, and 15.4 m<sup>2</sup> g<sup>-1</sup>, respectively. The specific surface areas were consistent with the crystallite sizes calculated by the results of XRD where Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod had the smallest Co<sub>3</sub>O<sub>4</sub> particle size at approximately 10.44 nm while that for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube (approximately 16.50 nm) was the largest. The larger specific surface area of CeO<sub>2</sub>-rod was beneficial for the dispersion of Co<sub>3</sub>O<sub>4</sub>, which was conducive to the catalytic performance.

Fig. 4 shows the Raman spectra of the CeO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated. For pure CeO<sub>2</sub> supports, a distinct vibrational mode (F<sub>2g</sub>) at 462 cm<sup>-1</sup> was observed, which was belong to the symmetrical stretching vibration of the CeO<sub>2</sub> phase [27]. The maximum half width (MHW) values of the F<sub>2g</sub> peaks were in the sequence of CeO<sub>2</sub>-rod > CeO<sub>2</sub>-plate > CeO<sub>2</sub>-cube. Generally, the higher MHW values of the F<sub>2g</sub> peaks, the higher concentrations of oxygen defects [18]. Thus, CeO<sub>2</sub>-rod had the highest concentration of oxygen defects, followed by CeO<sub>2</sub>-plate, and CeO<sub>2</sub>-cube had the least. The Raman spectra of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts had similarities with those of CeO<sub>2</sub> catalysts. However, the bands assigned to cobalt oxide species were not found, which revealed that they were well dispersed. In addition, the presence of Co led to not only a slight red-shift of F<sub>2g</sub> peaks from 462 to 443 cm<sup>-1</sup> but also the increase of the MHW values. The red-shift together with band broadening revealed the incorporation of Co ions into the surface of CeO<sub>2</sub> sup-

ports, but without changing the original CeO<sub>2</sub> cubic structure, which resulted in the increase of oxygen vacancies.

Fig. 5 shows the H<sub>2</sub>-TPR profiles of the CeO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated. It can be seen that the CeO<sub>2</sub> supports only showed two reduction peaks, while Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts showed three reduction peaks. For CeO<sub>2</sub> supports, the low-temperature reduction peak was assigned to the reduction of CeO<sub>2</sub> particles with small size while the high-temperature reduction peak was attributed to the reduction of particles with large size [28]. For Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, the former two reduction peaks at approximately 275 and 329 °C were assigned to the reduction of Co<sup>3+</sup> to Co<sup>2+</sup> and Co<sup>2+</sup> to Co<sup>0</sup>, respectively [29], while the last reduction peak was assigned to the reduction of CeO<sub>2</sub>. Similar profiles were also observed for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube, except that the reduction peaks shifted to higher temperatures. The results suggested that the interaction between Co<sub>3</sub>O<sub>4</sub> and CeO<sub>2</sub>-rod was the strongest among the three Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts. As well known, the stronger the interaction between Co<sub>3</sub>O<sub>4</sub> and CeO<sub>2</sub> supports, the higher the redox ability of cobalt species [30].

Fig. 6 shows the XPS spectra of Co 2p, Ce 3d, and O 1s for the Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated. As can be seen in Fig. 6(a), for the three Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts, two main peaks ascribed to Co 2p<sub>3/2</sub> and Co 2p<sub>1/2</sub> at 781.5–782.7 and 797.0–798.1 eV, respectively, with satellite peaks, were observed. The Co 2p<sub>3/2</sub> spectra could be decomposed into two characteristic peaks, of which the peak with the lower binding energy was corresponded to Co<sup>3+</sup>, while the peak with the high binding energy was related to Co<sup>2+</sup> [31]. According to Table 2, the proportion of Co<sup>3+</sup> to the total Co

DCeO<sub>2</sub>: CeO<sub>2</sub> crystallite size calculated by Scherrer equation from XRD.

DCo<sub>3</sub>O<sub>4</sub>: Co<sub>3</sub>O<sub>4</sub> crystallite size calculated by Scherrer equation from XRD.

Fig. 5. H<sub>2</sub>-TPR profiles of the CeO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated.

on Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube was 0.66, 0.63, and 0.59, respectively. Thus, the proportion of Co<sup>3+</sup> on Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod was higher than that on Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube, and it is believed that the better catalytic performance of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod is associated with the high content of Co<sup>3+</sup> [7].

Fig. 6(b) shows the XPS spectra of Ce 3d for the Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts investigated. The spectra of Ce 3d could be resolved into eight peaks, of which six peaks denoted as v, v<sub>2</sub>, v<sub>3</sub>, u, u<sub>2</sub>, and u<sub>3</sub> were assigned to Ce<sup>4+</sup>, while the other two peaks, denoted as v<sub>1</sub> and u<sub>1</sub>, were assigned to Ce<sup>3+</sup> [32]. According to Table 2, the proportion of Ce<sup>3+</sup> to the total Ce on Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube was 0.18, 0.15, and 0.11, respectively. It is reported that the transformation between Ce<sup>3+</sup> and Ce<sup>4+</sup> could produce oxygen vacancies in previous literatures, revealing that the higher the proportion of Ce<sup>3+</sup>, the more oxygen vacancies are formed [33]. Combined with the results of Raman spectroscopy, the oxygen vacancies of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod were more than those of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube. Therefore, it was likely that the better catalytic performance of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod was related to the higher proportion of Ce<sup>3+</sup>.

The O 1s XPS spectra of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube are shown in Fig. 6(c). The asymmetrical O 1s peak was divided into two components: one at BE = 528.8–529.1 eV was corresponded to the surface-lattice oxygen (O<sub>lat</sub>), and the other at BE = 531.2–531.6 eV was related to the surface-adsorbed oxygen (O<sub>ads</sub>) [7,34]. According to Table 2, the ratio of O<sub>ads</sub>/(O<sub>ads</sub> + O<sub>lat</sub>) for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod was higher than those for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube, revealing Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod had more surface adsorbed oxygen, which was beneficial for catalytic oxidation.

### 3.3. Analysis of products

It is learned that the desired decomposition products of brominated hydrocarbons are CO<sub>2</sub> and Br<sub>2</sub> or HBr. To our disappointments, almost none of the treatment technologies can achieve complete mineralization. In this study, the products after reaction at different temperature over Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate, and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube were determined by GCMS, which are shown in Tables 3, S1, and S2. As can be seen in Table 3, for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, the products were CO, CO<sub>2</sub>, HBr, and H<sub>2</sub>O at low temperatures (below 200 °C), while Br<sub>2</sub> was generated above 250 °C. Of particular note is that no other bromine products were generated at each

Fig. 6. XPS spectra of (a) Co 2p, (b) Ce 3d and (c) O 1s for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts: ① Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod, ② Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and ③ Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube.

evaluated temperature. Moreover, exactly the same results were also observed for Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube, as shown in Tables S1 and S2, respectively.

It is also necessary to investigate the selectivity to CO, CO<sub>2</sub>, HBr, and Br<sub>2</sub>. Fig. 7 shows the selectivity to CO, CO<sub>2</sub>, Br<sub>2</sub>, and HBr as a

**Table 2**  
XPS parameters of the  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated.

Catalyst	Surface composition (at.%)			$\text{Co}^{3+}/(\text{Co}^{2+} + \text{Co}^{3+})$	$\text{Ce}^{3+}/(\text{Ce}^{3+} + \text{Ce}^{4+})$	$\text{O}_{\text{ads}}/(\text{O}_{\text{ads}} + \text{O}_{\text{lat}})$	Co/Ce
	Co	Ce	O				
$\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod	0.71	6.89	53.54	0.66	0.18	0.25	0.13

$\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube	0.98	8.92	51.71	0.59	0.11	0.20	0.11

**Table 3**  
Products in outlet at different temperature over  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod.

Temperature (°C)	Detected substances
150	$\text{CH}_2\text{Br}_2$ , CO, $\text{CO}_2$ , HBr, $\text{H}_2\text{O}$
200	$\text{CH}_2\text{Br}_2$ , CO, $\text{CO}_2$ , HBr, $\text{H}_2\text{O}$
250	$\text{CH}_2\text{Br}_2$ , CO, $\text{CO}_2$ , HBr, $\text{Br}_2$ , $\text{H}_2\text{O}$
300	$\text{CH}_2\text{Br}_2$ , CO, $\text{CO}_2$ , HBr, $\text{Br}_2$ , $\text{H}_2\text{O}$
350	CO, $\text{CO}_2$ , HBr, $\text{Br}_2$ , $\text{H}_2\text{O}$
400	CO, $\text{CO}_2$ , HBr, $\text{Br}_2$ , $\text{H}_2\text{O}$
450	CO, $\text{CO}_2$ , HBr, $\text{Br}_2$ , $\text{H}_2\text{O}$

function of temperature over the  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts investigated. It was found that their selectivity were different, depending on the catalysts used. As can be seen in Fig. 7(a), for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube, when the temperature increased, the selectivity to CO and HBr gradually decreased, while that to  $\text{CO}_2$  and  $\text{Br}_2$  gradually increased. Similar results were also observed for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod. The increase of  $\text{CO}_2$  was due to further oxidation of CO, and the generation of  $\text{Br}_2$  might be assigned to the Deacon reaction ( $4\text{HBr} + \text{O}_2 = 2\text{Br}_2 + 2\text{H}_2\text{O}$ ) [7]. For  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube, the selectivity to  $\text{CO}_2$  and  $\text{Br}_2$  were approximately 76% and 54%, respectively, at 350 °C, while the selectivity to  $\text{CO}_2$  and  $\text{Br}_2$  were approximately 80% and 65%, respectively, at 350 °C for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate, and approximately 84% and 69%, respectively, at 350 °C for  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod. The results revealed that  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod had the highest selectivity to  $\text{CO}_2$  and  $\text{Br}_2$  among the three  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts.

### 3.4. The effect of water or p-xylene (PX)

Water vapor usually exists in the PTA exhaust gas, and it is necessary to consider the resistance of the catalyst to humidity. Thus, the  $\text{CH}_2\text{Br}_2$  oxidation was performed in the presence of 2 vol%  $\text{H}_2\text{O}$ . As shown in Fig. 8 at low temperatures, the  $\text{CH}_2\text{Br}_2$  conversion slightly increased when  $\text{H}_2\text{O}$  was present, and T-10 (the temperature needed for 10% conversion) decreased by approximately 10 °C. It was most likely that the promotional effect of  $\text{H}_2\text{O}$  on  $\text{CH}_2\text{Br}_2$  oxidation at low temperatures was on account of the removal of surface bromine species, based on the reverse Deacon reaction:  $\text{H}_2\text{O} + \text{Br}^- \rightleftharpoons \text{HBr} + \text{OH}^-$  [3]. However, a decrease in  $\text{CH}_2\text{Br}_2$  conversion was observed at high temperatures, due to the occupation of  $\text{H}_2\text{O}$  on a part of active sites.

Commonly, there are many organic compounds in PTA exhaust gas. However, it is not realistic to simultaneously study the effect of all of the organic compounds on  $\text{CH}_2\text{Br}_2$  oxidation. Hence, we mainly focused on the characteristics of reactions involving binary organic pollutants. Thus, the effect of p-xylene (PX) on  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod was also investigated. As shown in Fig. 8, the  $\text{CH}_2\text{Br}_2$  conversion was obviously inhibited when PX was present, both at low and high temperatures, and T-90 shifted to 355 °C, which might be due to the decrease of oxygen species caused by consumption of surface-active oxygen during PX oxidation.

**Fig. 7.** Selectivity to CO,  $\text{CO}_2$ ,  $\text{Br}_2$ , and HBr as a function of temperature over  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube (a),  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate (b), and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod (c).

**Fig. 8.** The effect of water or p-xylene (PX) on  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod;  $\text{CH}_2\text{Br}_2$  alone: 500 ppm  $\text{CH}_2\text{Br}_2$ ;  $\text{CH}_2\text{Br}_2 + \text{H}_2\text{O}$ : 500 ppm  $\text{CH}_2\text{Br}_2 + 2 \text{ vol}\% \text{H}_2\text{O}$ ;  $\text{CH}_2\text{Br}_2 + \text{PX}$ : 500 ppm  $\text{CH}_2\text{Br}_2 + 500 \text{ ppm PX}$ ; in all cases, 10%  $\text{O}_2$  and  $\text{N}_2$  balance;  $\text{GHSV} = 75,000 \text{ mL}/(\text{g}\cdot\text{h})^{-1}$ .

**Fig. 10.** Stability test of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod in the presence of 2 vol% water at  $300^\circ\text{C}$ .

**Fig. 11.** *In situ* DRIFTS spectra of  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{CeO}_2$ -rod (a, b) and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod (c, d) catalysts at different temperatures.

### 3.5. Catalyst stability

To examine the catalytic stability, a long-duration  $\text{CH}_2\text{Br}_2$  oxidation test was performed at a constant temperature. The on-stream evolution of  $\text{CH}_2\text{Br}_2$  conversion with time at  $300\text{ }^\circ\text{C}$  for  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts with different  $\text{CeO}_2$  morphologies is shown in Fig. 9. Within 30 h,  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod presented a stable conversion of approximately 82%. During the long-duration  $\text{CH}_2\text{Br}_2$  oxidation test, the selectivity of product was nearly constant, revealing that the composition and structure of the active component was stable. In addition, there is a popular belief that the catalytic activity of Co-based catalyst is reduced due to the accumulation of Br species. XPS analysis (Fig. S4) indicated the deposition of only 1.2% Br on the surface of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod after 30 h of reaction, which might be ascribed to the fast reaction of Br species on the surface of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod. Moreover,  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -plate and  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -cube also showed good catalytic stability. The results revealed that all of the three  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts were stable for  $\text{CH}_2\text{Br}_2$  oxidation.

The stability of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod in the presence of 2 vol% water at  $300\text{ }^\circ\text{C}$  was also investigated. As shown in Fig. 10, the  $\text{CH}_2\text{Br}_2$  conversion was always stabilized at approximately 82% within the first 3 h. Then, after the introduction of  $\text{H}_2\text{O}$  (2 vol%), an apparent decrease in  $\text{CH}_2\text{Br}_2$  conversion from 82% to 62% occurred, revealing that  $\text{H}_2\text{O}$  showed a suppression effect on the catalytic reaction, on account of the competitive adsorption of  $\text{CH}_2\text{Br}_2$  and  $\text{H}_2\text{O}$  on the active sites. The catalytic activity of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod was stabilized within 24 h. When  $\text{H}_2\text{O}$  was cut off, the  $\text{CH}_2\text{Br}_2$  conversion basically regained its value of 82%. The results revealed that the catalytic activity of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod was sustainable and showed good resistance to water-penetration.

### 3.6. In situ DRIFTS studies

To get a deep insight into the catalytic behaviors of  $\text{CeO}_2$  and  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts, *in situ* DRIFTS experiments were carried out, and the results are displayed in Fig. 11. As can be seen in Fig. 11(a, b), for  $\text{CeO}_2$ -rod, after treated in the mixture of 500 ppm  $\text{CH}_2\text{Br}_2$ , 10%  $\text{O}_2$ , and  $\text{N}_2$  at  $50\text{ }^\circ\text{C}$  for 1 h, the DRIFTS spectra exhibited bands at 3070, 2985, 1595, 1560, and  $1198\text{ cm}^{-1}$ . The bands at 3070, 2985, and  $1198\text{ cm}^{-1}$  were assigned to antisymmetric stretching, symmetric stretching, and wagging of methylene species ( $-\text{CH}_2-$ ), respectively, in  $\text{CH}_2\text{Br}_2$  molecules [35]. When the temperature increased, these bands gradually decreased in intensities and could not be observed above  $100\text{ }^\circ\text{C}$ , revealing either desorption or reaction of  $\text{CH}_2\text{Br}_2$  molecules. The band at  $1560\text{ cm}^{-1}$  was ascribed to the formate species ( $-\text{COOH}$ ) [7]. The band at  $1595\text{ cm}^{-1}$  was attributed to  $\text{H}_2\text{O}$  on the surface of  $\text{CeO}_2$  [36], which was gradually removed when the temperature increased. In addition, the removal of the bands assigned to  $\text{CH}_2\text{Br}_2$

molecules was along with the appearance of some new bands at 2933, 2876, 2850, 2819, 2719, 1539, 1369, and  $1360\text{ cm}^{-1}$ . The bands at 2876, 2850, 2719, 1539, 1369, and  $1360\text{ cm}^{-1}$  (including 1527 and  $1344\text{ cm}^{-1}$  developed at 350 and  $400\text{ }^\circ\text{C}$ ) were assigned to the formate species ( $-\text{COOH}$ ) [3,37,38], while the other bands at 2933 and  $2819\text{ cm}^{-1}$  were related to methyl antisymmetric stretching and symmetric stretching of the methoxy species ( $-\text{CH}_3\text{O}$ ), respectively [39]. All of the bands generated with the decomposition of the adsorbed  $\text{CH}_2\text{Br}_2$ , revealing that the formate and methoxy species were the main intermediate products produced on the surface of  $\text{CeO}_2$ -rod.

On the basis of *in situ* DRIFTS experiments, a believable reaction pathway for  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{CeO}_2$  is shown in Fig. S5. The reaction pathway is described as follows: (1) A  $\text{CH}_2\text{Br}_2$  molecule is adsorbed on oxygen vacancies through two bromine atoms. (2) The two bromine atoms are extracted by the adjacent nucleophilic oxygen, forming bidentate methoxy species, which were not observed due to their instability. (3) Formate and methoxy species are formed by the Cannizzaro type disproportionation of bidentate methoxy species. (4) The formate and methoxy species are further oxidized by active oxygen species to produce CO and  $\text{CO}_2$ .

In the case of  $\text{Co}_3\text{O}_4/\text{CeO}_2$ -rod (Fig. 11(c, d)), the similar DRIFTS spectra were observed at 50, 100, 150, 200, and  $250\text{ }^\circ\text{C}$ , except that some bands assigned to the formate species disappeared and a new band was observed at  $1489\text{ cm}^{-1}$ , assigned to scissoring of methylene species ( $-\text{CH}_2-$ ) [39], which revealed that the reaction pathway was not fundamentally changed by the addition of Co. When the temperature increased, the band intensity was decreased obviously at  $250\text{ }^\circ\text{C}$  and complete disappeared at  $300\text{ }^\circ\text{C}$ . The results revealed that the presence of Co further promoted the decomposition of intermediate species at high temperatures. Furthermore, no bands corresponding to CO,  $\text{CO}_2$ , and HBr as the final products could be observed, due to the quick desorption of these species.

For  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts, the dissociation of C-Br and C-H bonds was easier on account of the electrophilicity and high valence of  $\text{Co}_3\text{O}_4$ , and the high catalytic activity was ascribed to the strong interaction between  $\text{Co}_3\text{O}_4$  and  $\text{CeO}_2$ . In the process of reaction,  $\text{Co}^{3+}$  was reduced to  $\text{Co}^{2+}$ , after which the lattice oxygen of  $\text{CeO}_2$  transferred to Co to reoxidize  $\text{Co}^{2+}$  to  $\text{Co}^{3+}$ . At the same time,  $\text{CeO}_2$  released lattice oxygen that could be quickly reoxidized by gas-phase oxygen due to its excellent oxygen storage capacity. To get a deeper understanding of the reaction, a credible reaction mechanism for  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts, consisting of five steps, is schematized in Fig. 12: (1) A  $\text{CH}_2\text{Br}_2$  molecule is adsorbed on oxygen vacancies through two bromine atoms. (2) The two bromine atoms are extracted by the adjacent nucleophilic oxygen, forming bidentate methoxy species, which were not observed due to their instability. (3) The gas-phase oxygen is adsorbed on the catalyst surface to supplement the con-

Fig. 12. A credible reaction mechanism for  $\text{CH}_2\text{Br}_2$  oxidation over  $\text{Co}_3\text{O}_4/\text{CeO}_2$  catalysts.

sumed oxygen. (4) Formate and methoxy species are formed by the Cannizzaro type disproportionation of bidentate methoxy species. (5) Formate and methoxy species are further oxidized by active oxygen species to generate CO and CO<sub>2</sub>. Additionally, the Br species are quickly removed from the Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> surface in the form of Br<sub>2</sub> by the Deacon reaction (4HBr + O<sub>2</sub> = 2Br + HBr), or in the form of HBr by the chemical reaction of the dissociatively adsorbed Br and surface hydroxyl groups.

#### 4. Conclusions

Three Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts with different CeO<sub>2</sub> morphologies (rod, plate, and cube) were prepared by the hydrothermal and impregnation methods, and the morphology effect of CeO<sub>2</sub> on the catalytic performance of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts for CH<sub>2</sub>Br<sub>2</sub> oxidation, used as the model compound for brominated hydrocarbons, was investigated. Among the three Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts, Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod achieved significantly higher catalytic activity, with a T-90 of approximately 312 °C for CH<sub>2</sub>Br<sub>2</sub> oxidation and higher selectivity to CO<sub>2</sub> than Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-plate and Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-cube. The HRTEM images revealed that the Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod predominantly exposed {100} and {110} planes. Based on the results of Raman and XPS, the Co, Ce valences, surface oxygen species, and oxygen vacancies were dependent on morphology. The high catalytic activity of Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod was attributed to the high content of Co<sup>3+</sup>, more surface-adsorbed oxygen, and more oxygen vacancies related to their exposed {100} and {110} planes. In addition, Co<sub>3</sub>O<sub>4</sub> had a strong interaction with CeO<sub>2</sub>-rod, making it superior for CH<sub>2</sub>Br<sub>2</sub> oxidation. The results of long-duration stability experiments confirmed that Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub>-rod could be considered as an excellent catalyst for CH<sub>2</sub>Br<sub>2</sub> oxidation. Moreover, on the basis of the analysis of products and *in situ* DRIFTS studies, a credible reaction mechanism for CH<sub>2</sub>Br<sub>2</sub> oxidation over Co<sub>3</sub>O<sub>4</sub>/CeO<sub>2</sub> catalysts was proposed.
